Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) has caused the rapidly unfolding coronavirus disease 2019 (COVID-19) pandemic^{1,2}. Clinical manifestations of COVID-19 vary, ranging from asymptomatic infection to respiratory failure. The mechanisms determining such variable outcomes remain unresolved. Here, we investigated SARS-CoV-2 spike glycoprotein (S)-reactive CD4⁺ T cells in peripheral blood of patients with COVID-19 and SARS-CoV-2-unexposed healthy donors (HD). We detected SARS-CoV-2 S-reactive CD4⁺ T cells in 83% of patients with COVID-19 but also in 35% of HD. S-reactive CD4⁺ T cells in HD reacted primarily to C-terminal S epitopes, which show a higher homology to spike glycoproteins of human endemic coronaviruses, compared to N-terminal epitopes. S-reactive T cell lines generated from SARS-CoV-2-naïve HD responded similarly to C-terminal S of human endemic coronaviruses 229E and OC43 and SARS-CoV-2, demonstrating the presence of S-cross-reactive T cells, probably generated during past encounters with endemic coronaviruses. The role of pre-existing SARS-CoV-2 cross-reactive T cells for clinical outcomes remains to be determined in larger cohorts. However, the presence of S-cross-reactive T cells in a sizable fraction of the general population may affect the dynamics of the current pandemic, and has important implications for the design and analysis of upcoming COVID-19 vaccine trials.

The COVID-19 pandemic poses an unprecedented threat to public health and the global economy with ever-increasing cases and COVID-19-related deaths worldwide^{1,2}. COVID-19 is routinely diagnosed by detection of SARS-CoV-2 RNA in nasopharyngeal swabs via PCR³, which works reliably in the acute phase of COVID-19^{4,5}. However, limited test availability and preferential testing of symptomatic patients has likely lead to significant underestimation of infection burden and overestimation of case-fatality rates⁶. Serological analysis of SARS-CoV-2-induced humoral immunity could reveal asymptomatic infections, but it is not yet widely applied^{7,8} and complicated by the fact that coronavirus-induced antibody responses are quite variable and rather short-lived^{9,10}. Coronavirus-induced cellular immunity is predicted to be more sustained, but poorly characterized so far. However, several T cell epitopes in coronavirus structural proteins have been predicted or identified^{9,11–13}. Importantly, T helper cell

responses and generation of neutralizing antibodies may be interdependent^{9,14}. Studies of the SARS-CoV epidemic in 2002/03 have shown that adaptive immune responses directed against spike glycoprotein were protective^{9,15,16}. Hence, induction of SARS-CoV-2-specific CD4⁺ T cells is likely to be critical in the instruction of affinity matured and potentially protective antibody responses¹⁷. We therefore examined the presence, frequencies and phenotypic characteristics of SARS-CoV-2 spike glycoprotein (S)-reactive T cells in COVID-19 patients compared to SARS-CoV-2 unexposed healthy donors (HD).

Identification of S-reactive CD4⁺ T cells

We identified S-reactive CD4⁺ T cells by flow cytometry according to their expression of CD40L and 4-1BB after *in vitro* stimulation with S

peptides. To this end, we designed two peptide pools (15 amino acids (aa), 11 aa overlaps) spanning the entire S that comprised different amounts of putative MHC-II epitopes based on identified epitopes in SARS-CoV^{11–13} (Fig. 1a). SARS-CoV-2 S peptide pool PepMixTM 1 (henceforth: S-I) spans the N-terminal part (aa residues 1–643) including 21 predicted SARS-CoV MHC-II epitopes (Fig. 1a, Extended Data Fig. 1, Extended Data Table 1). The second peptide pool PepMixTM 2 (S-II) covered the C-terminal portion (amino acid residues 633–1273) including 13 predicted SARS-CoV MHC-II epitopes (Fig. 1a, Extended Data Fig. 1, Extended Data Table 1). The peptides of the receptor-binding domain (RBD) in the subunit S1, which represents a major target of neutralizing antibodies, are included in S-I^{18,19}.

For antigen-specific stimulation, PBMC from patients and HD (see patient and HD characteristics: Table 1, Extended Data Table 2 and 3) were stimulated for 16 hours with S-I and S-II peptide pools, respectively. Antigen-reactive CD4⁺ T cells were identified by co-expression of 4-1BB and CD40L, which allows for sensitive detection of S-reactive CD4⁺ T cells re-activated by TCR engagement *ex vivo*^{20–22} (Fig. 2a, Extended Data Fig. 2, and Supplementary File). In 12 (67%) and 15 (83%) of 18 patients we detected CD4⁺ T cells reacting against the S-I and the S-II peptide pool, respectively (Fig. 2b, d, e). Most COVID-19 patients with critical disease exhibited no reactivity to S-I (Extended Data Fig. 3).

Remarkably, S-II-reactive CD4⁺ T cells, albeit at slightly lower frequencies compared with patients, could also be detected in 24 of 68 HD (35%), henceforth referred to as reactive healthy donors (RHD) (Fig. 2c, d, e). S-I-reactive CD4⁺ T cells could only be detected in 6 out of the 24 RHD, i.e. in 5.8% of all HD (Fig. 2d, e). All HD were negative for IgG antibodies specific for S subunit 1 (S1) in contrast to patients (Fig. 2f). We further ruled out early SARS-CoV-2 infection at initial sampling by 1) direct PCR standard diagnosis in 10 RHD (data not shown), 2) serological testing (Fig. 2f) and 3) by repeated serological testing at least 28 days later for 65 of 68 HD (Extended Data Fig. 4).

We further phenotypically and functionally characterized S-reactive CD4⁺ T cells in additional patients (Extended Data Table 4) and RHD. Notably, in both groups, SARS-CoV-2 S-II-reactive CD4⁺ T cells exhibited a memory phenotype and a significant proportion of the cells expressed IFN γ , indicative of T_H1 polarization (Fig. 2g, Extended Data Fig. 5a–d). Most S-reactive CD4⁺ T cells expressed IL-2 but only few expressed IL-17A (Extended Data Fig. 5a–d). Frequencies of S-II-reactive CD4⁺ T cells expressing IFN γ were similar in patients and RHD (Fig. 2g). Testing for TNF α expression revealed that S-II reactive IFN γ ⁺ CD4⁺ T cells from RHD mostly co-expressed TNF α , whereas S-II reactive IFN γ ⁺ CD4⁺ T cells from P displayed rather heterogeneous TNF α expression patterns (Extended Data Figure 5e). This is likely reflecting the different disease stages during the acute SARS-CoV-2 infection of the individual patients included in our study. These results demonstrate the presence of S-reactive CD4⁺ T cells with a predominantly T_H1 memory phenotype not only in COVID-19 patients but also in seronegative SARS-CoV-2 unexposed HD.

S-reactive CD4⁺ T cells in RHD are cross-reactive to HCoV-229E and OC43

S-reactive CD4⁺ T cells from COVID-19 patients equally targeted both, the N-terminal (S-I) and C-terminal peptide pools (S-II) of S, while S-reactive CD4⁺ T cells from RHD reacted significantly stronger to S-II (Fig. 2d). S-II exhibits a higher homology to human endemic “common cold” coronaviruses (HCoVs) 229E, NL63, OC43, and HKU1 with regard to the SARS-CoV MHC-II epitopes, as compared to peptide pool S-I (Extended Data Table 1 and Extended Data Fig. 1). This suggests that S-reactivity in SARS-CoV-2 naïve HD originated from previous immune responses to HCoVs. We therefore tested 18 of the 68 HD for the presence of antibodies specific for the four endemic HCoVs. We detected IgG antibodies against all four HCoVs in all tested HD, regardless of the presence of measurable S-reactive CD4⁺ T cells (Extended Data Fig. 6a). Frequencies of S-(cross)-reactive CD4⁺ T cells in RHD did not

correlate with antibody levels against HCoVs potentially indicating that they have not been generated very recently. Similar findings have been obtained for other anti-viral CD4⁺ T cell responses, for example following yellow fever vaccination (YFV-17D). CD4⁺ T cell responses showed a significant correlation with the later generation of high titers of neutralizing antibodies only at very early time points after YFV-17D vaccination²³.

We next determined whether SARS-CoV-2 S-reactive CD4⁺ T cells in RHD correlated with a CD4⁺ T cell response to spike glycoprotein of endemic HCoVs (S_{HCoV}). To this end, PBMC from HD and RHD were stimulated with S-I and S-II pools from SARS-CoV-2 and S_{HCoV}-I and S_{HCoV}-II (spike glycoprotein subunit 1 and subunit 2 peptide pool, respectively) of OC43 and 229E (Fig. 2h, and Extended Data Fig. 6b–d), respectively. There was a strong positive correlation of CD4⁺ T cell reactivity against S-II and S_{HCoV}-II of OC43 and 229E ($r=0.629$, $r=0.715$, Fig. 2h), respectively, while there was no or only a weak negative correlation detected between S-I reactivity and reactivity towards S_{HCoV}-I of OC43 and 229E, respectively ($r=0.037$, $r=-0.259$) (Extended Data Fig. 6b). No correlation was observed between reactivity towards S-I/S-II and CMVpp65 (Extended Data Fig. 6c, d).

Next, we tested whether S-reactive CD4⁺ T cells of RHD responded to stimulation with S_{HCoV}. To this end, from three RHD (RHD01, 07 and 15), S-II-reactive CD4⁺ T cells were isolated, expanded *ex vivo* for 12 days and subsequently re-stimulated with S_{HCoV}-I and S_{HCoV}-II of OC43 and 229E, with the S-II pool as positive control, and S-I and a peptide pool from CMVpp65 as negative controls (Fig. 2i, j). Restimulation with the SARS-CoV-2 S-II peptide pool induced the highest frequencies of 4-1BB⁺CD40L⁺ CD4⁺ T cells, while negligible responses were measured in the negative controls (S-I, CMVpp65, unstimulated), demonstrating the high specificity of the established S-II reactive CD4⁺ T cell lines (Fig. 2j). In contrast, strong responses were observed against S_{HCoV}-II peptide pools of the two HCoVs (Fig. 2j). These findings provide evidence that cross-reactivity of SARS-CoV-2 S-II-reactive cells to S_{HCoV} in the tested RHD, suggesting that pre-existence of SARS-CoV-2 reactive T cells in seronegative naïve individuals originates from prior immune responses to endemic HCoVs.

Specific activation signatures in COVID-19 patients

Finally, we assessed additional activation marker profiles on S-reactive T cells from COVID-19 patients and RHD. Expression of CD38, HLA-DR and Ki-67 has previously been shown to reliably characterize recently *in vivo* activated human T cells during acute and chronic infection^{24–28}. Notably, S-reactive CD4⁺ T cells from patients largely expressed CD38, HLA-DR and Ki-67 (Fig. 3a–d). The majority of S-reactive T cells in patients co-expressed CD38 and HLA-DR (Fig. 3e), characteristic for effector T cell responses during acute viral infections^{24,26}, whereas CD38 and Ki-67 co-expression was more variable (Fig. 3f). By contrast, S-reactive CD4⁺ T cells from RHD did not express CD38, HLA-DR and Ki-67, or only at low frequencies (Fig. 3b–f), and co-expression was not observed (Fig. 3e, f). In patients, considerable proportions of the entire peripheral CD4⁺ and CD8⁺ T cell populations co-expressed CD38 and HLA-DR (data not shown), which, however, could not be re-activated with our S peptide pools *in vitro*. These findings are in line with results of a recent study showing refractory T cell signatures in COVID-19 patients²⁹. Additionally, a proportion of these CD38⁺HLA-DR⁺ CD4⁺ T cells likely targets other structural proteins of SARS-CoV-2. We furthermore show that the presence of S-reactive CD4⁺ T cells and in particular of CD38-expressing cells among S-reactive CD4⁺ T cells exhibited a high variability among patients in the course of COVID-19 disease (Fig. 3g, h).

Discussion

Our study demonstrates the presence of S-reactive CD4⁺ T cells in COVID-19 patients, and in a considerable proportion of SARS-CoV-2

unexposed HD. In light of the recent emergence of SARS-CoV-2, our data raise the intriguing possibility that such pre-existing S-reactive T cells represent cross-reactive clones, probably acquired in previous infections with endemic HCoVs. HCoVs account for approximately 20% of “common cold” upper respiratory tract infections, are ubiquitous, but display a winter seasonality^{30–32}. Based on epidemiological data, it may be extrapolated that adults contract an HCoV infection on average every two to three years. Protective antibodies may wane mid-term but cellular immunity could remain^{13,33}. Although the overall amino acid sequence homology of S is relatively low compared to spike glycoproteins of HCoVs, there is an overlap of MHC-II epitopes especially in the C-terminal domain of the here used peptide pools (Fig. 1a, Extended Data Fig. 1). This may explain the preferential reactivity of CD4⁺ T cells to the C-terminal domain in one third of HD.

The biological role of pre-existing S-cross-reactive CD4⁺ T cells in 35% of HD remains unclear for now. However, assuming that these cells have a protective role in SARS-CoV-2 infection, they may contribute to understanding the divergent manifestations of COVID-19, and the striking resilience of children and young adults to symptomatic SARS-CoV-2 infection. Especially children in day care centers but also young adults have more frequent social contacts than elderly, and thus may have a higher HCoV prevalence. This hypothesis requires further investigation in future longitudinal studies assessing the presence of pre-existing SARS-CoV-2-cross-reactive CD4⁺ T cells and their impact on the susceptibility to SARS-CoV-2 infection and age-related clinical outcomes of COVID-19.

SARS-CoV neutralizing antibodies are associated with convalescence, and they have been detected 12 months after disease⁹. However, the durability of neutralizing antibody responses against SARS-CoV-2 remains unknown. Although antibodies against HCoV can wane within months after infection, HCoV re-infection is accompanied by low-level and short-lived virus shedding with only mild symptoms of short duration pointing towards humoral-independent residual immunity¹⁰. Cellular immunity has not yet been studied in this context. In mouse models, however, CD4⁺ as well as CD8⁺ T cell responses directed against structural proteins such as spike or nucleocapsid protein of SARS-CoV critically contributed to viral clearance^{15,34,35}. Understanding the extent to which and how SARS-CoV-2-specific humoral or cellular immunity mediates durable protection against reinfection is of critical importance in the coming months.

Our study reveals pre-existing cellular SARS-CoV-2-cross-reactivity in a substantial proportion of SARS-CoV-2 seronegative HD. This finding might have significant epidemiological implications regarding herd immunity thresholds and projections for the COVID-19 pandemic. Our results provide a decisive rationale to initiate worldwide prospective studies to assess the contribution of pre-existing, potentially region-dependent SARS-CoV-2-cross-reactive immunity to the diverse clinical outcomes of SARS-CoV-2 infections. Together with currently introduced novel serological tests, the data generated by such studies may critically inform evidence-based risk evaluation, patient monitoring, adaptation of containment methods, and last but not least, vaccine development.

Fig. 1 | Structural domains, homology and MHC-II epitopes of the SARS-CoV-2 spike glycoprotein. a, SARS-CoV-2 spike glycoprotein (1237 amino acids (aa)) is separated at the cleavage site (CS) into subunit S1 harboring the receptor-binding domain (RBD) and subunit S2 containing the fusion peptide (FP), the transmembrane domain (TM) and the cytoplasmic peptide (CP). Sequence homology of spike glycoprotein of SARS-CoV-2 to SARS-CoV and HCoV strains NL63, 229E, HKU1 and OC43 was calculated as percentage of aa identity in sliding windows of 10 aa and is depicted as grey vertical scale bars. Predicted SARS-CoV MHC-II epitopes are indicated as small horizontal lines

below and sequences and references are listed in Extended Data Table 1. Homology is depicted for each reported MHC-II epitope in Extended Data Figure 1. SARS-CoV-2 PepMix™ 1 (N-term) (in the main text referred to as S-I) spans over the N-terminal and SARS-CoV-2 PepMix™ 2 (C-term) (in the main text referred to as S-II) spans over the C-terminal part of S, as indicated above the alignment. **b,** Proportion of sequence identity of the N-terminal and C-terminal parts of SARS-CoV-2 spike glycoprotein to the spike glycoproteins of HCoV strains NL63, 229E, HKU1 and OC43.

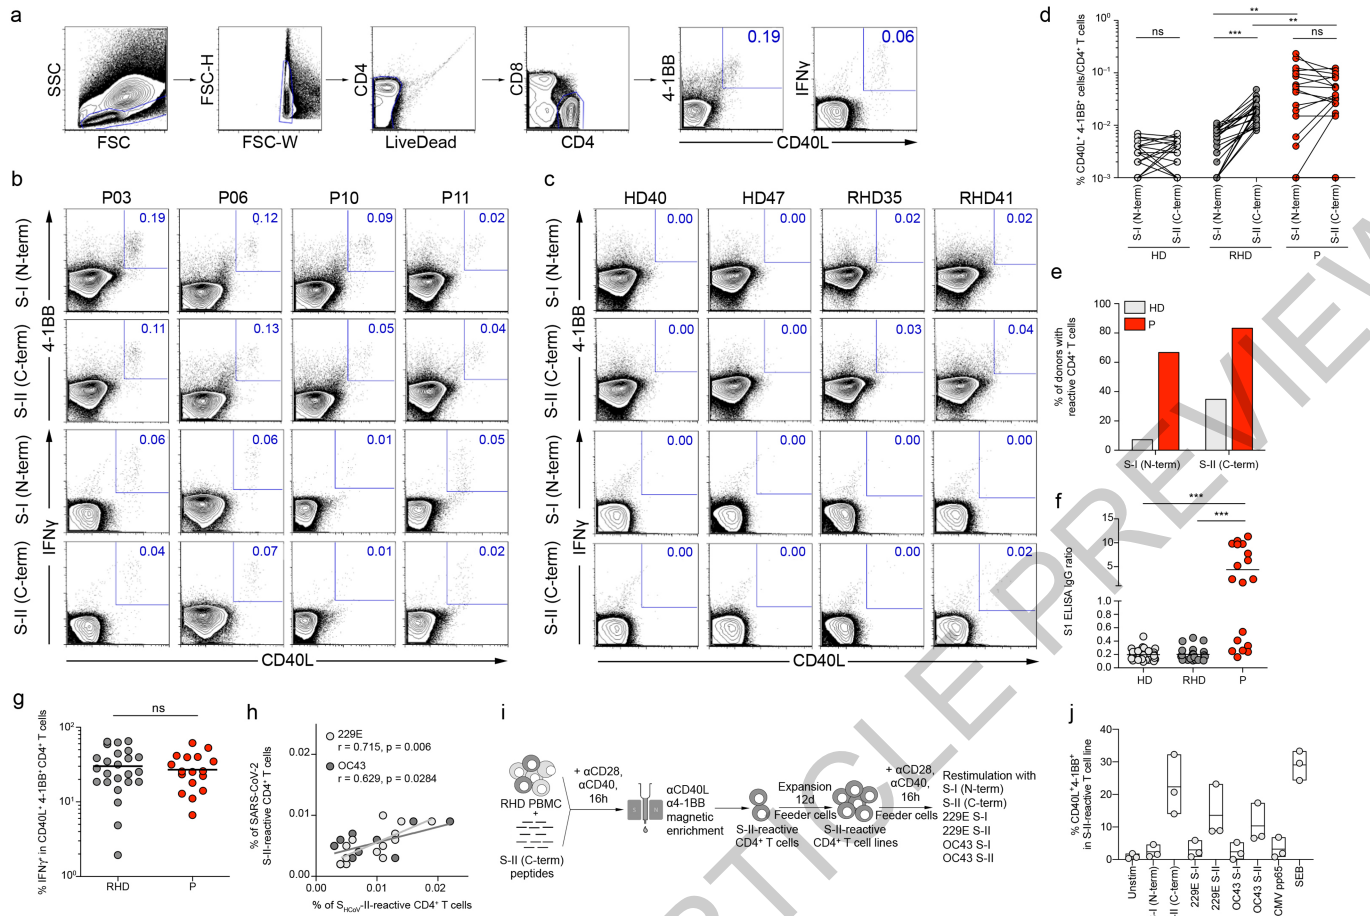

Fig. 2 | SARS-CoV-2 spike glycoprotein-reactive CD4⁺ T cells in COVID-19 patients and healthy donors.

a, Gating strategy to detect SARS-CoV-2 S-reactive CD4⁺ T cells after 16 hours *in vitro* stimulation with PepMix™ SARS-CoV-2 spike glycoprotein peptide pool 1 (S-I (N-term)) and 2 (S-II (C-term)). Representative data of one COVID-19 patient is depicted.

b, c, Representative plots displaying CD40L and 4-1BB as well as CD40L and IFN-γ expression on CD4⁺ T cells of COVID-19 patients (P), healthy donors (HD) and reactive healthy donors (RHD) after 16 hours *in vitro* stimulation with S-I (N-term) or S-II (C-term). Numbers are percent of double-positive cells from total CD4⁺ T cells.

d, Comparison of S-I (N-term)- or S-II (C-term)-reactive CD40L⁺ 4-1BB⁺ CD4⁺ T cell frequencies of HD (n=44), RHD (n=24) and P (n=18). *p*-values (from left to right and top to bottom): ns: 0.1632, ***: <0.0001, **: 0.0031, **: 0.0059, ns: 0.9766.

e, Percent of individuals from P and HD, respectively, with S-I (N-term)- and S-II (C-term)-reactive CD4⁺ T cells,

respectively. **f**, SARS-CoV-2 S-I serology of HD (n=44), RHD (n=24) and P (n=18). *p*-values: upper ***: <0.0001, lower ***: <0.0001. **g**, Comparison of frequencies of IFN-γ⁺ cells among CD40L⁺ 4-1BB⁺ CD4⁺ T cells in RHD (n=24) and P (n=18).

h, Correlation between SARS-CoV-2 S-II and S-HCoV-II CD4⁺ T cell responses. Frequencies of CD40L⁺ 4-1BB⁺ CD4⁺ T cells after stimulation with S-II peptide pools of SARS-CoV-2 (y-axis) and S-II peptide pools of HCoVs (x-axis) 229E (lightgrey, n=12) and OC43 (darkgrey, n=9) from RHD are shown.

i, Schematic summary of SARS-CoV-2 S-II-reactive CD4⁺ T cell lines generation. Enriched and expanded SARS-CoV-2 S-II-reactive CD4⁺ T cells were re-stimulated with the indicated S-I and S-II peptide pools of SARS-CoV-2 and the two HCoV strains. Statistics: **d, f, g**, **p*<0.05, ***p*<0.01, ****p*<0.001 as calculated by two-tailed Mann-Whitney U test; **i**, Correlation coefficient *r* was calculated by bivariate Pearson correlation and the related *p* value based on t-distribution.

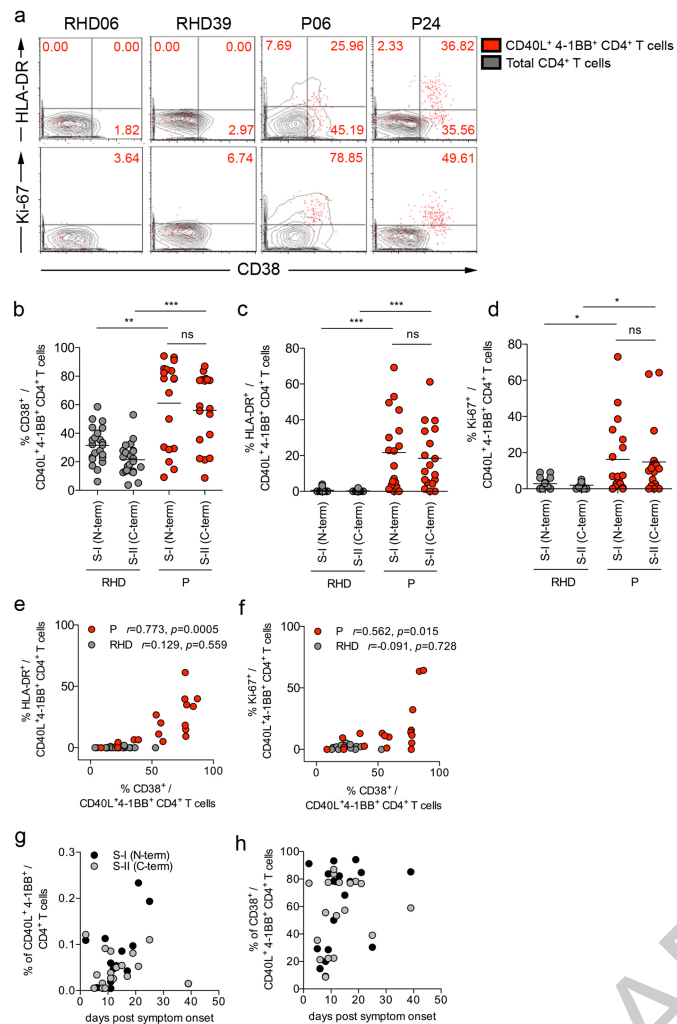

Fig. 3 | CD38, HLA-DR and Ki-67 expression of SARS-CoV-2 S-I- and S-II-reactive CD4⁺ T cells discriminates SARS-CoV-2 patients from reactive healthy donors. a, Representative examples of HLA-DR and Ki-67 expression plotted against CD38 expression on S-II-reactive CD4⁺ T cells (red dots) compared to total CD4⁺ T cells (grey contours) in reactive healthy donors (RHD) and COVID-19 patients (P). **b-d**, Comparison of frequencies of CD38⁺, HLA-DR⁺ and Ki-67⁺ cells among S-I (N-term)- and S-II (C-term)-reactive CD4⁺ T cells in RHD (**b,c**, $n=23$; **d**, $n=17$) and P ($n=18$). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ as calculated by two-tailed Mann-Whitney U test. *p*-values (from left to right): **b**) **: 0.0060, ***: <0.0001, ns: 0.2482; **c**) ***: <0.0001, ***: <0.0001, ns: 0.8618; **d**) *: 0.0405, *: 0.0102, ns: 1.00. **e,f**, Co-expression of HLA-DR or Ki-67 and CD38 among S-II-reactive CD4⁺ T cells from RHD (**e**, $n=23$; **f**, $n=17$) and P ($n=18$). **g,h**, Frequencies of S-I- and S-II-reactive CD40L⁺4-1BB⁺CD4⁺ T cells (**g**) or CD38⁺ among S-II-reactive CD4⁺ T cells (**h**) of P ($n=18$) plotted against days post symptom onset. Statistics: **b-d**, * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ as calculated by two-tailed Mann-Whitney U test; **e,f**, Correlation coefficient *r* was calculated by bivariate Pearson correlation and the related *p* value based on t-distribution.

Table 1 | Baseline characteristics of COVID-19 patients and healthy donors

Cohort	m:f	Age Avg (range)	severity	ICU (y/n)	Sampling day Avg (range)
COVID-19 patients	72 : 28%	52.6 (21-81 yrs)	mild 38.9% severe 27.8% critical 33.3%	n 44.4% y 55.6%	14.9 (2-39)
Healthy donors	31 : 59%	41.9 (20-64 yrs)	-	-	-

*Day after onset of symptoms, Avg: average, m: male, f: female, ICU: intensive care unit, y: yes, n: no.

Methods

Study subjects

The study was approved by the Institutional Review board of the Charité (EA2/066/20). After providing written informed consent, 68 healthy donors (HD, Extended Data Table 3, Table 2) and 18 and 7 additional COVID-19 patients (Table 1 and Extended Data Table 2 and 4) were included in the study. COVID-19 patients who tested positive for SARS-CoV-2 RNA in nasopharyngeal swabs were recruited at Charité Campus Virchow-Klinikum, Berlin, between March 1st and April, 2nd 2020. All COVID-19 patients were enrolled in the Berlin prospective observation COVID-19 study (PA-COVID-19)³⁶. Disease severity was grouped based on requirement for supplemental oxygen or ventilation (mild; hospitalized, no supplemental oxygen, severe: hospitalized, supplemental oxygen (including High-flow), critical: hospitalized, invasive ventilation). For intracellular cytokine and memory T cell stainings, 7 additional COVID-19 patients (Extended Data Table 4) were enrolled at later time points and 5 RHD were re-recruited. To retrospectively validate SARS-CoV-2 seronegativity, all HD were re-invited between 4th and 7th May 2020 for re-assessment of anti-S1 IgG titers. 65 of 68 could be re-recruited and all were seronegative for SARS-CoV-2 (Extended Data Fig. 4).

Serology

Anti-SARS-CoV-2 IgG ELISA was performed using a commercial kit (EUROIMMUN) as described and validated before³⁷. Recombinant immunofluorescence assays (rIFA) to determine IgG titers against HCoV were performed by using VeroB4 cells expressing cloned recombinant coronavirus spike proteins from HCoV-229E, HCoV-NL63, HCoV-OC43, HCoV-HKU1 as described in Corman et al.³⁸.

Cell isolation and stimulation

Peripheral blood mononuclear cells (PBMC) were isolated from heparinized whole blood by gradient density centrifugation according to manufacturer's instructions (Leucosep tubes, Greiner; Biocoll, Bio&SELL). Stimulation was conducted with 5×10^6 PBMC in RPMI 1640 medium (Gibco) supplemented with 10% heat inactivated AB serum (Pan Biotech), 100 U/ml penicillin (Biochrom), 0.1 mg/ml streptomycin (Biochrom) and PepMixTM SARS-CoV-2 spike glycoprotein (JPT) peptide pool 1 or 2 in the presence of 1 μ g/ml purified anti-CD28 (clone CD28.2, BD Biosciences). The PepMixTM SARS-CoV-2 spike glycoprotein pool 1 covering the N-terminal amino acid (aa) residues 1-643 (abbreviated to "S-I" (N-term)) contained 158 15-mers overlapping by 11 aa. PepMixTM SARS-CoV-2 spike glycoprotein pool 2 covered the C-terminal aa residues 633-1273 (abbreviated to "S-II" (C-term)) containing 156 15-mers overlapping by 11 aa and one 17-mer at the C-terminus, i.e. 157 peptides in total. Both peptide pools were used at 1 μ g/ml per peptide, respectively. Further details on the peptide pools and predicted MHC-II epitopes are given in Fig. 1, Extended Data Fig. 1 and Extended Data Table 1. Stimulation controls were performed with equal concentrations of DMSO in PBS (unstimulated) or 1.5 mg SEB/1.0 mg TSST1 (Sigma-Aldrich) and PepMixTM HCMVA (pp65) (>90%; CMVpp65) (JPT) in the presence of 1 μ g/ml purified anti-CD28 (clone CD28.2, BD Biosciences) as positive controls, respectively. Incubation was performed at 37 °C, 5% CO₂ for 16 h with 10 μ g/ml brefeldin A (Sigma-Aldrich) added after 2 h. Stimulation was stopped by incubation in 2 mM EDTA for 5 min. Stimulation with HCoV spike glycoprotein (S_{HCoV}) peptide pools was conducted under the described conditions above but with 1 μ g/ml per peptide of the following peptide pools: PepMixTM HCoV-229E spike glycoprotein pool 1 or 2 or PepMixTM HCoV-OC43 spike glycoprotein pool 1 or 2 (all JPT).

Flow Cytometry

After stimulation, surface stainings were conducted for 15 min with the following fluorochrome conjugated antibodies titrated to their optimal concentrations: CD38-PE-Vio770 (clone REA671, Miltenyi, dilution:

1:400), CD69-APC-Cy7 (FN50, Biolegend, 1:100), HLA-DR-VioGreen (REA805, Miltenyi, 1:50), CD4-BrilliantViolet605 (RPA-T4, Biolegend, 1:200), CD8-PerCP (SK1, Biolegend, 1:100) with 1 mg/ml Beriglobin (CSL Behring) added prior to the staining. For exclusion of dead cells, Zombie Yellow fixable viability staining (Biolegend) was added for the last 10 min of incubation. Fixation and permeabilization were performed with eBioscienceTM FoxP3 fixation and PermBuffer (Invitrogen) according to the manufacturer's protocol and intracellular staining carried out for 30 min in the dark at room temperature with Beriglobin added prior to staining with 4-1BB(CD137)-PE (clone 4B4-1, BD, 1:10), CD40L(CD154)-APC (5C8, Miltenyi, 1:40), IFN γ -AlexaFluor700 (B27, BD, 1:50), TNF α -PacificBlue (MAB11, Biolegend, 1:100) and Ki-67-AlexaFluor488 (B56, BD, 1:100). To assess naive/memory T cell phenotypes and cytokine expression, the following antibodies were used: surface staining was performed with CD3-V500 (SP34-2, BD, 1:50), CD8-PerCP (SK1, Biolegend, 1:100), CD4-BrilliantViolet605 (RPA-T4, Biolegend, 1:200), CCR7-AlexaFluor488 (G043H7, Biolegend, 1:150), CD45RA-PE-Cy7 (HII00, Biolegend, 1:200), IFN γ -AlexaFluor700 (B27, BD, 1:100), CD40L(CD154)-BrilliantViolet421 (24-31, Biolegend, 1:200), IL-2-APC (S344.111, BD, 1:200), 4-1BB(CD137)-PE (4B4-1, BD, 1:10) and IL-17A-APC-Cy7 (BL168, Biolegend, 1:20) were utilized for intracellular staining after fixation and permeabilization using BD FACSLysing Buffer and BD Perm2 Buffer, according to manufacturer's instructions. Samples were measured on a MACSQuant[®] Analyzer 16 using MACSQuantify software (v2.13). Instrument performance was monitored daily with Rainbow Calibration Particles (BD).

Cell enrichment, expansion, and restimulation

S-II-reactive T cells were enriched by magnetic cell sorting (MACS) from PBMC stimulated with PepMixTM SARS-CoV-2 spike glycoprotein peptide pool 2 (JPT) in the presence of 1 μ g/ml purified anti-CD28 (clone CD28.2, BD Biosciences) and 1 μ g/ml a-CD40 (clone 5C3, Biolegend). Following stimulation for 16 h, cells were stained with CD40L-APC and 4-1BB-PE and firstly enriched with anti-APC MultiSort MicroBeads (Miltenyi) according to manufacturer's instructions. After the release of anti-APC-MicroBeads, a second enrichment was performed with anti-PE MicroBeads (Miltenyi). Purity was checked each time to >80% of alive cells. APC feeder cells were generated by CD3 MicroBead (Miltenyi) depletion of the CD40L-APC-negative fraction and subsequent inactivation by irradiation at 50Gy. The irradiated feeder cells were co-cultured with the enriched 4-1BB⁺CD40L⁺ T cells at a ratio of 1:1 in RPMI 1640 medium (Gibco) supplemented with 10% heat inactivated AB serum (Pan Biotech), 100 U/ml penicillin (Biochrom), 0.1 mg/ml streptomycin (Biochrom) in the presence of 10 ng/ml IL-7 and IL-15, respectively (both Miltenyi) for 12 days followed by 2 day cytokine starvation prior to restimulation. Restimulation was conducted with the described conditions above and additionally with 1 μ g/ml per peptide of the following peptide pools: PepMixTM HCoV-229E spike glycoprotein pool 1 or 2 or PepMixTM HCoV-OC43 spike glycoprotein pool 1 or 2 (all JPT).

Data analysis and statistics

Sequence alignments have been performed using R (v3.6.1) including package ClustalX³⁹ and using the Needleman-Wunsch algorithm⁴⁰. Flow cytometry data were analyzed with FlowJo 9.9.6 (FlowJo LLC). Microsoft Excel (v14.1.0) and Prism 5 and 8 (GraphPad Inc.) was used for plotting and statistical analysis. In stimulation experiments, frequencies of activated CD4⁺ T cells were background-subtracted, with the frequency in the unstimulated control sample representing the background. Non-parametric testing was used to compare cell frequencies and antibody titers between groups (two-tailed Mann-Whitney U test). *n* indicates the number of donors.

Reporting summary

Further information on research design is available in the Nature Research Reporting Summary linked to this paper.

Data availability

All flow cytometry data are made available in the FlowRepository.org (experiment ID: FR-FCM-Z2K3). An additional Supplementary Figure displaying the individual gating strategy for all donors is available in the online version of the paper.

Acknowledgements We thank Ulf Klein (Leeds, UK) und Hans-Peter Herzel (Berlin) for critical discussion. We thank S. O. and J. S. for discussions and support. We thank Toralf Kaiser and Jenny Kirsch from the Flow Cytometry Core Facility (FCCF) of the DRFZ for expert technical help. We thank Bernd Timmerman from the Sequencing Core Facility of the Max Planck Institute for Molecular Genetics for discussion. This work was supported by the German Research Foundation (KFO339 to JB and FF, SFB-TR84 projects A4, B6 to SH, B8 to MM, C6 to MW, C8, C10 to LES, C9 to MW, NS) and by the German Federal Ministry of Education and Research (BMBF-RAPID to SH, CD, and CAPSyS to MW, NS). This work was additionally funded by the Federal Ministry of Health through a resolution of the German Bundestag to AT, JB, LH and MD.

Author contributions JB, LL and MF planned and performed experiments and analyzed the data. DW, PG, JR, MD, BK, FF, EB, MM, LH performed experiments. FK, AH, SH, KB, ID, MAM, SV, MW, NS, CD, LES managed initial patient contacts, designed and supervised clinical management and clinical data. MAM and VMC planned and performed experiments and analyzed the data. JS and SM established high-throughput analysis. RL designed experiments. FK, UR and HW established new reagents. GCT and AT designed and supervised the study. CGT, LES and AT wrote the manuscript.

Competing interests FK, UR and HW are employed at JPT Peptide Technologies, who have provided peptide pools for this work. FK also part-owns and is inventor on a patent describing the use of overlapping peptide pools for the stimulation of T cells. Until this patent expires, he will receive royalties on JPT PepMix sales. JS and SM are employed at Miltenyi Biotec, who provided reagents and devices for this study. All other authors declare no competing interests.

Extended Data Fig. 1 | Homology of reported MHC-II epitopes from Extended Data Table 1 in the spike glycoprotein of SARS-CoV to SARS-CoV-2 and endemic coronavirus strains. Shown is for each epitope the respective

section from a global sequence alignment between the 6 indicated coronaviruses. Identical residues are color-coded from white (no identity) to red (100% identity).

COVID-19 Patients

Reactive Healthy Donors

Healthy Donors

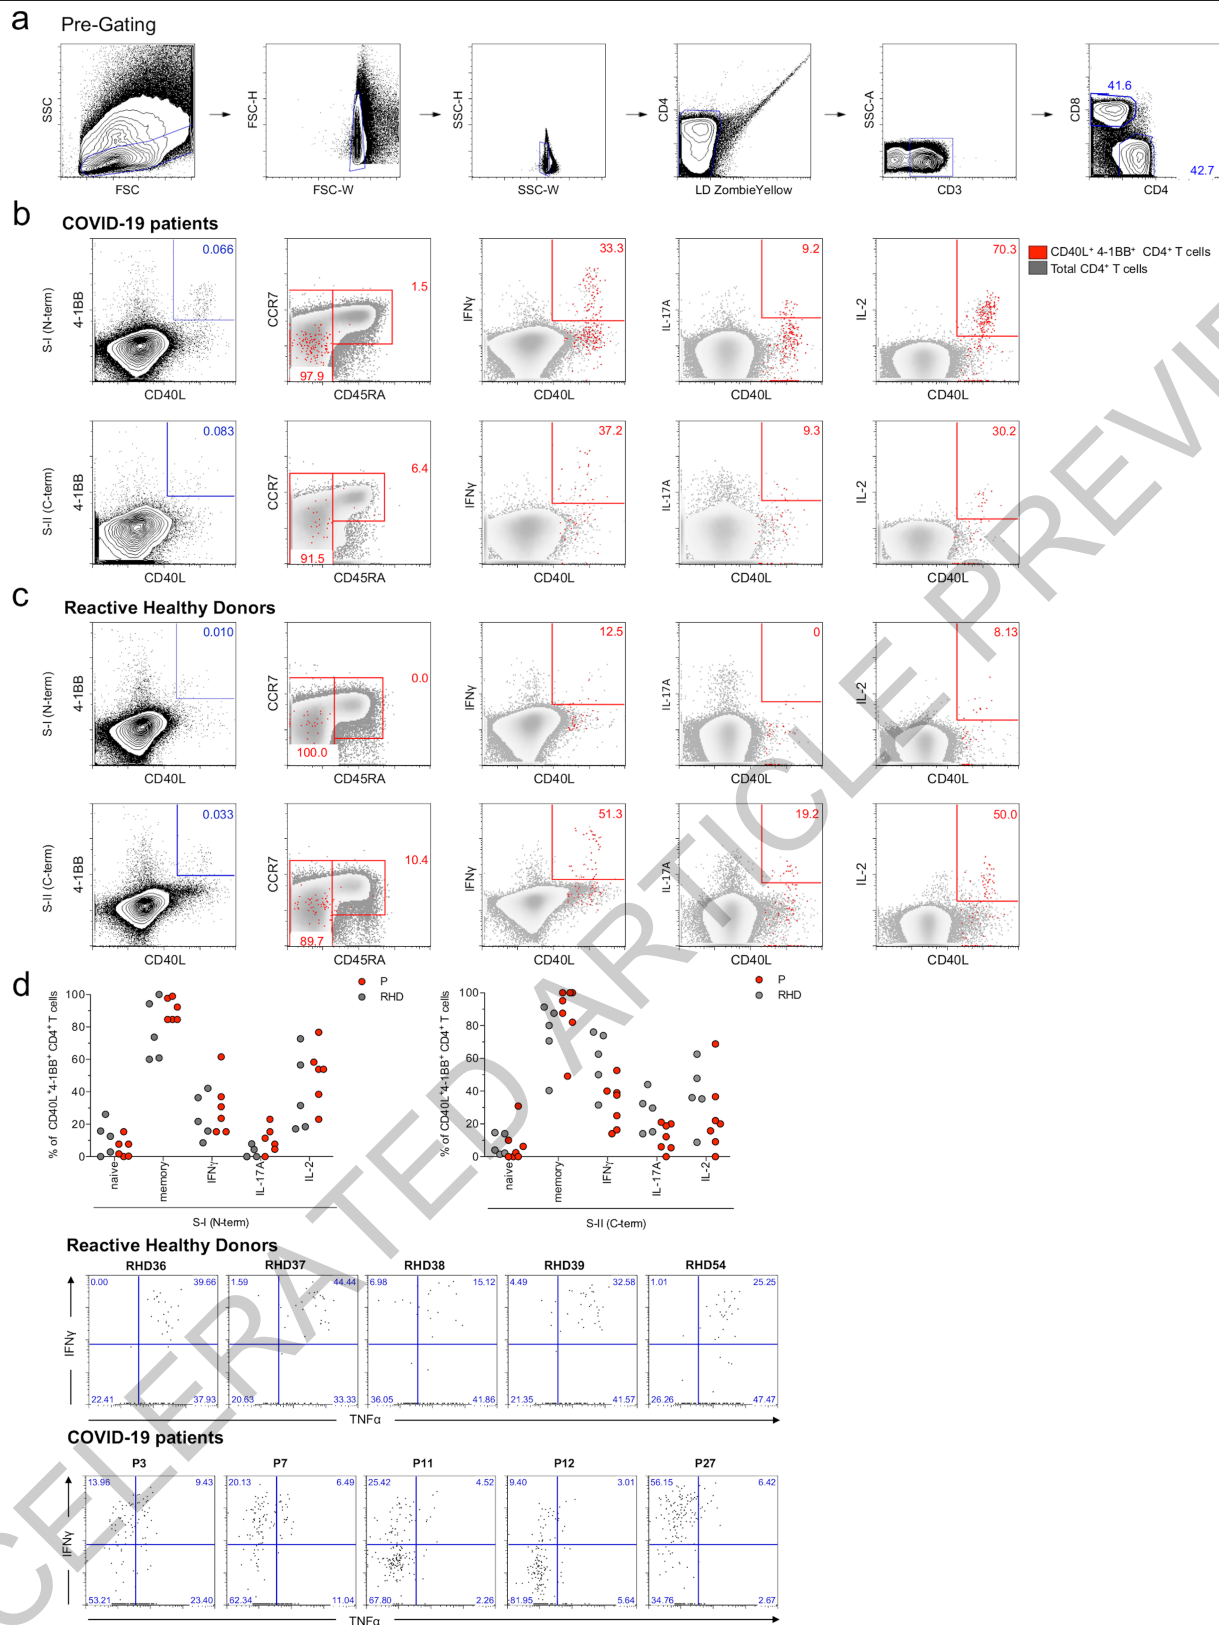

Extended Data Fig. 2 | Overview of the analyses gates and dot plots from COVID-19 patients, reactive healthy donors (RHD) and healthy donors (HD) to determine the frequencies of S-I- and S-II-reactive CD4⁺ T cells and the ratios of CD38⁺, HLA-DR⁺ and Ki-67⁺ cells among them.

Extended Data Fig. 3 | Most S-I- and S-II-non-reactive COVID-19 patients had a critical disease stage. Frequencies of S-I- and S-II-reactive CD4⁺ T cells in COVID-19 patients are grouped according to disease severity in mild ($n=7$), severe ($n=5$) and critical ($n=6$).

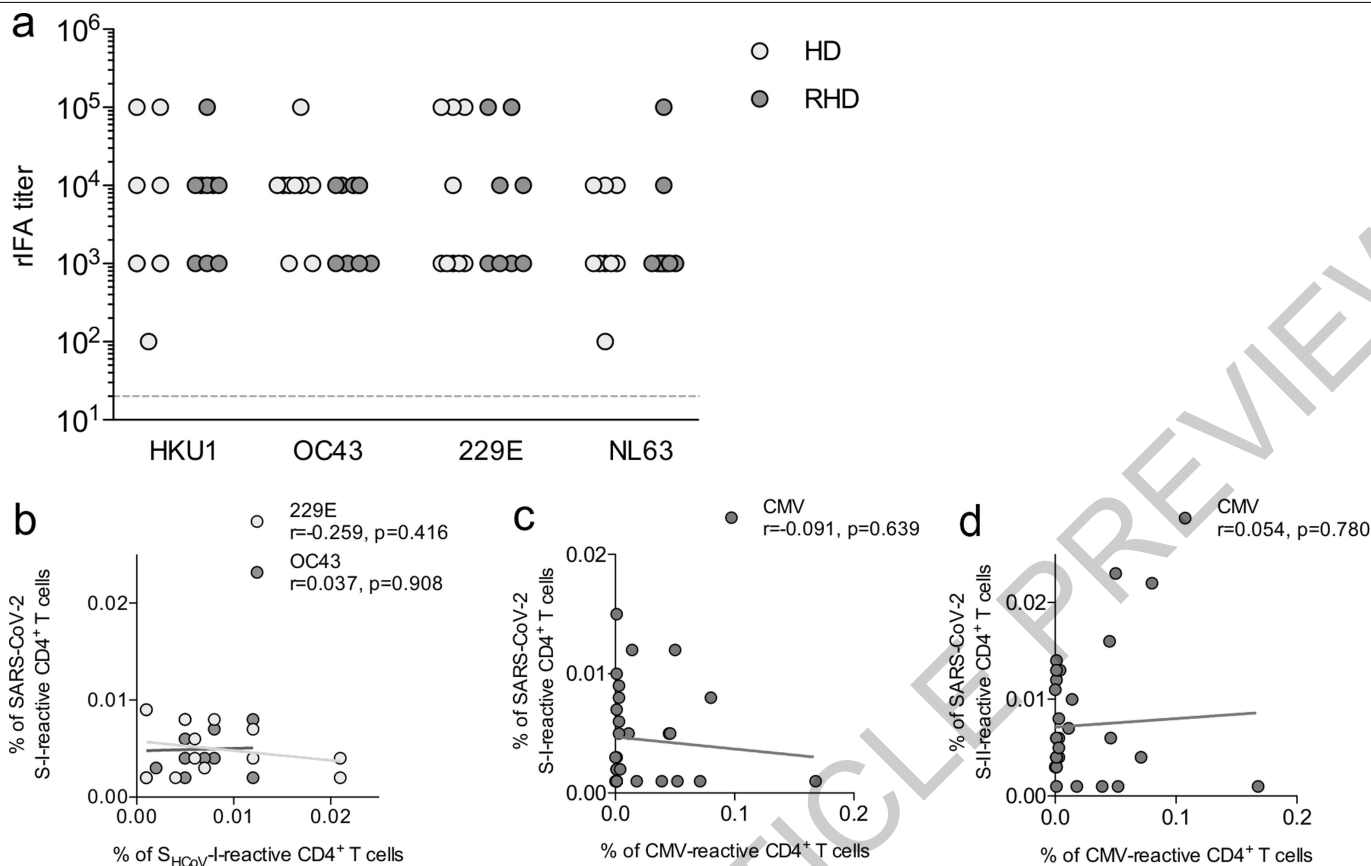

Extended Data Fig. 4 | Repeated serology of HD confirms unexposed status of HD and RHD. SARS-CoV-2 S1 serology of HD (n=43) and RHD (n=22) more than 28 days after initial sampling. Anti-spike glycoprotein subunit 1 (S1) IgG titers are expressed as ratio normalized to calibrator well.

Extended Data Fig. 5 | Cytokine and differentiation marker expression of S-I- and S-II-reactive CD40L⁺4-1BB⁺CD4⁺ T cells from COVID-19 patients and RHD. **a, Gating scheme of one representative donor to select CD3⁺CD4⁺ T cells and exclude dead cells and doublets. **b**, **c**, Determination of the differentiation marker and cytokine profile of S-I-/S-II-reactive CD4⁺ T cells exemplarily shown for one COVID-19 patient (P) and one reactive healthy donor (RHD) after S-I and S-II peptide pool stimulation, respectively. SARS-CoV-2-reactive CD4⁺ T cells were defined by CD40L and 4-1BB expression post stimulation and are displayed as red dots in the subsequent dotplots. Numbers are the frequencies**

of cytokine expressing cells of S-I-/S-II-reactive CD4⁺ T cells and distribution between naïve (CCR7⁺CD45RA⁺) and memory (CCR7⁺CD45RA⁺) phenotype of S-I-/S-II-reactive CD4⁺ T cells, respectively. **d**, Diagrams summarizing the cytokine and differentiation marker distribution frequencies of S-I- and S-II-reactive CD4⁺ T cells from seven patients and five RHD. **e**, Expression of TNFα and IFNγ in S-II-reactive CD4⁺ T cells in P and RHD. Five representative plots of TNFα versus IFNγ expression in CD40L⁺4-1BB⁺CD4⁺ T cells in reactive healthy donors (RHD) and COVID-19 patients (P), gating strategy as shown in Fig. 2.

Extended Data Fig. 6 | HCoV-specific IgG antibody titres in HD and RHD and specificity of SARS-CoV-2-reactive T cells in HD. a) IgG antibody titres against endemic coronavirus strains (HCoV). VeroB4 cells expressing recombinant spike (S) proteins of HCoV-HKU1, HCoV-OC43, HCoV-229E and HCoV-NL63, respectively, were used in a recombinant immunofluorescence assay (rIFA) as outlined in Corman et al. 2012. Titers above 1:20 dilution were considered positive (indicated by dashed line). HD: healthy donor ($n=9$); RHD: reactive healthy donor ($n=9$). **b-d**, Frequencies of SARS-CoV-2 S-I-reactive $CD4^+$ T cells in healthy donors do not correlate with frequencies of S_{HCoV} -I-reactive or

CMV-reactive $CD4^+$ T cells and frequencies of SARS-CoV-2 S-II-reactive $CD4^+$ T cells in healthy donors do not correlate with frequencies of CMV-reactive $CD4^+$ T cells **b**, Scatter plot of S_{HCoV} -I-reactive $CD4^+$ T cell (for 229E ($n=12$) and OC43 ($n=9$)), respectively) and SARS-CoV-2 S-I-reactive $CD4^+$ T cell frequencies. **c**, Scatter plot of SARS-CoV-2 S-I-reactive $CD4^+$ T cell and CMV-reactive $CD4^+$ T cell frequencies ($n=21$). **d**, Scatter plot of SARS-CoV-2 S-II-reactive $CD4^+$ T cell and CMV-reactive $CD4^+$ T cell frequencies ($n=21$). Statistics: **c-d**, Correlation coefficient r was calculated by Pearson correlation and the related p value based on t-distribution.

Reporting Summary

Nature Research wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Research policies, see [Authors & Referees](#) and the [Editorial Policy Checklist](#).

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

- | | |
|-------------------------------------|--|
| n/a | Confirmed |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> The exact sample size (<i>n</i>) for each experimental group/condition, given as a discrete number and unit of measurement |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> The statistical test(s) used AND whether they are one- or two-sided
<i>Only common tests should be described solely by name; describe more complex techniques in the Methods section.</i> |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> A description of all covariates tested |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals) |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> For null hypothesis testing, the test statistic (e.g. <i>F</i> , <i>t</i> , <i>r</i>) with confidence intervals, effect sizes, degrees of freedom and <i>P</i> value noted
<i>Give P values as exact values whenever suitable.</i> |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings |
| <input checked="" type="checkbox"/> | <input type="checkbox"/> For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes |
| <input type="checkbox"/> | <input checked="" type="checkbox"/> Estimates of effect sizes (e.g. Cohen's <i>d</i> , Pearson's <i>r</i>), indicating how they were calculated |

Our web collection on [statistics for biologists](#) contains articles on many of the points above.

Software and code

Policy information about [availability of computer code](#)

Data collection	Miltenyi MACSquantify software v2.13 was used for flow cytometry data collection.
Data analysis	All the softwares and there version information are shown her. FlowJo (v9.9.6) was used for all FACS analyses. Microsoft Excel (v.14.1.0) was used to collect and arrange data and patient / donor information. GraphPad Prism (v5.0b and v8.4.2. (464)) was used to analyze data and create plots. Sequence alignments have been performed using R (v3.6.1) including package ClustalX (Larkin,M.A., Blackshields, G., Brown, N.P., Chenna, R., McGettigan, P.A., McWilliam, H., Valentin, F., Wallace, I.M., Wilm, A., Lopez, R., Thompson, J.D., Gibson, T.J., Higgins, D.G. (2007) Clustal W and Clustal X version 2.0. Bioinformatics, 23:2947-2948.) and using the Needleman-Wunsch algorithm (Needleman S., Wunsch C. (1970) A general method applicable to the search for similarities in the amino acid sequence of two proteins. Journal of Molecular Biology, 48(3): 443-453).

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors/reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Research [guidelines for submitting code & software](#) for further information.

Data

Policy information about [availability of data](#)

All manuscripts must include a [data availability statement](#). This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A list of figures that have associated raw data
- A description of any restrictions on data availability

All flow cytometry data are made available in the FlowRepository.org (experiment ID: FR-FCM-Z2K3). An additional Supplementary Figure displaying the individual gating strategy for all donors is available in the online version of the paper.

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

☒ Life sciences ☐ Behavioural & social sciences ☐ Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see [nature.com/documents/nr-reporting-summary-flat.pdf](https://www.nature.com/documents/nr-reporting-summary-flat.pdf)

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

Sample size	No sample size calculation was performed. Within COVID-19 patients, 83% exhibited T cell reactivity to the Spike glycoprotein of SARS-CoV-2. Within the healthy donors recruited, 35% were identified as reactive healthy donors. With these proportions, the recruited numbers of subjects are sufficient.
Data exclusions	No data were excluded from the analyses.
Replication	We remeasured several donors (accompanied by anti-SARS-CoV-2 IgG antibody testing) at later timepoints and used another Spike glycoprotein peptide pool from Miltenyi to ensure reproducibility of T cell reactivity in SARS-CoV-2 naive donors.
Randomization	No randomization was performed since it was not applicable to the study.
Blinding	Blinding was not applicable to this study.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

 anti-CD28 BD Biosciences Cat#555725, RRID:AB_396068

Validation

All antibodies are established, well described and published elsewhere. Informations are accessible on the manufacturers websites under Catalogue or RRID numbers.

Human research participants

Policy information about [studies involving human research participants](#)

Population characteristics	The study included: - 18 COVID-19 patients (age mean 52.6, range: 21-81 yrs; gender: female ratio 27.8%; sampling day (post symptom onset): mean 14.9, range: 2-39) - 68 healthy donors (age mean 41.93, range: 20-64 yrs; gender: female ratio 59%) All healthy donors stated to be free of symptoms indicating an acute infection.
Recruitment	Patients were hospitalised in the Charité. The patients were selected based on disease severity to achieve a balanced representation of the three disease severity groups.
Ethics oversight	Institutional Review Board of the Charité.

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Flow Cytometry

Plots

Confirm that:

- ☒ The axis labels state the marker and fluorochrome used (e.g. CD4-FITC).
- ☒ The axis scales are clearly visible. Include numbers along axes only for bottom left plot of group (a 'group' is an analysis of identical markers).
- ☒ All plots are contour plots with outliers or pseudocolor plots.
- ☒ A numerical value for number of cells or percentage (with statistics) is provided.

Methodology

Sample preparation	Peripheral blood mononuclear cells (PBMC) were isolated from heparinized whole blood by gradient density centrifugation according to manufacturer's instructions (Leucosep tubes, Greiner; Biocoll, Bio&SELL). Stimulation was conducted with 5x10 ⁶ PBMC in RPMI 1640 medium (Gibco) supplemented with 10% heat inactivated AB serum (Pan Biotech), 100 U/ml penicillin (Biochrom), 0.1 mg/ml streptomycin (Biochrom), and PepMixTM SARS-CoV-2 in the presence of 1 µg/ml purified anti-CD28 (clone CD28.2, BD Biosciences). PepMixTM SARS-CoV-2 (Spike Glycoprotein) subpool 1 covering the N-terminal aa 1-643 (abbreviated to "S-I (N-term)") containing 158 15-mers overlapping by 11 and PepMixTM SARS-CoV-2 (Spike Glycoprotein) subpool 2 covering the C-terminal aa 633-1273 (abbreviated to "S-II (C-term)") (JPT) containing 156 15-mers overlapping by 11 and one 17-mer at C-terminus were used at 1 µg/ml per peptide, respectively. Stimulation controls were performed with equal concentrations of DMSO in PBS (unstimulated) or 1.5 mg SEB/1.0 mg TSST1 (Sigma-Aldrich) and PepMixTM CMV pp65 (Miltenyi) as positive controls, respectively. Incubation was performed at 37°C, 5% CO ₂ for 14h with 10 µg/ml brefeldin A (Sigma- Aldrich) added after 2 h. Stimulation was stopped by incubation in 20 mM EDTA for 5 min and surface staining conducted for 15 min with the following fluorochrome conjugated antibodies titrated to their optimal concentrations: CD38-PE-Vio770 (clone REA671, Miltenyi), CD69-APC-Cy7 (FN50, Biolegend), HLAD-DR-VioGreen (REA805, Miltenyi), CD4-BrilliantViolet605 (RPA-T4, Biolegend), CD8-PerCP (SK1, Biolegend) with 1 mg/ml Beriglobin (CSL Behring) added prior to the staining. For exclusion of dead cells, Zombie Yellow fixable viability staining (Biolegend) was added for the last 10 min of incubation. Fixation and permeabilization were performed with eBioscienceTM FoxP3 fixation and PermBuffer (Invitrogen) according to the manufacturer's protocol and intracellular staining carried out for 30 min in the dark at room temperature with Beriglobin added prior to intracellular staining with 4-1BB-PE (clone 4B4-1, BD), CD40L-APC (5C8, Miltenyi) and Ki-67-AlexaFluor488 (B56, BD). For intracellular cytokine staining, we employed different antibodies. Surface staining was performed with CD3-V500 (SP34-2, BD), CD8-PerCP (SK1, Biolegend), CD4-BrilliantViolet605 (RPA-T4, Biolegend), CCR7-AlexaFluor488 (G043H7, Biolegend), CD45RA-PE-Cy7 (HI100, Biolegend), IFN-γ-AlexaFluor700, CD40L-BrilliantViolet421 (24-31, Biolegend), IL-2-APC (5344.111, BD), 4-1BB-PE (4B4-1, BD) and IL-17A-APC-Cy7 (BL168, Biolegend) were utilized for intracellular staining after fixation and permeabilization using BD FACSLysing Buffer and BD Perm2 Buffer, according to manufacturer's instructions.
Instrument	Samples were measured on a MACSQuant® Analyzer 16 and the instrument performance monitored daily with Rainbow Calibration Particles (BD).
Software	Miltenyi MACSquantif software (v2.13) and FlowJo (v9.9.6)
Cell population abundance	Cells have not been enriched or sorted. Data are shown within ex vivo stimulated peripheral blood mononuclear cells.
Gating strategy	All recorded events were gated according to FSC and SSC as lymphocytes; single cells were further selected using FSC-H vs. FSC-W and again using SSC-H vs. SSC-W. Subsequently living cells were identified as ZombieYellow negative cells gated against CD4-BV605. An artefact population in some samples (probably induced by DMSO) was observed disturbing data analysis and was gated out using V500 vs V450. The subsequent gating scheme is depicted in Fig.2a and Fig. 3a.

- ☒ Tick this box to confirm that a figure exemplifying the gating strategy is provided in the Supplementary Information.
